Underwater Cellular Network Deployment in Singapore

Overview

The need for reliable underwater communication is growing rapidly as the number of subsea assets increases. From autonomous underwater vehicles (AUVs) performing offshore inspections to divers conducting critical missions, continuous communication and tracking are essential for safety, efficiency, and mission success.

To address this, Subnero, in collaboration with ST Engineering Unmanned & Integrated Systems (ST UIS), carried out one of the first commercial deployments of underwater networks designed for resource sharing between multiple users from defense, commercial, and research domains, much like the Internet.

Key Goals

- ✓ Demonstrate the feasibility of underwater cellular networking, adapting terrestrial cellular principles for subsea communication.
- ✓ Enable continuous two-way communication and tracking of subsea assets such as AUVs across multiple coverage zones.
- ✓ Validate multi-user network resource sharing, supporting defense, commercial, and research operations within a unified subsea network.

ST Engineering is a global technology, defence, and engineering group providing innovative solutions across aerospace, smart city, and digital systems domains. Through its Unmanned & Integrated Systems business, the company develops advanced communication and autonomous technologies that enhance connectivity and mission effectiveness in complex environments. Its capabilities in system integration and reliable field operations make ST Engineering a key partner in advancing underwater communication and networked maritime systems.

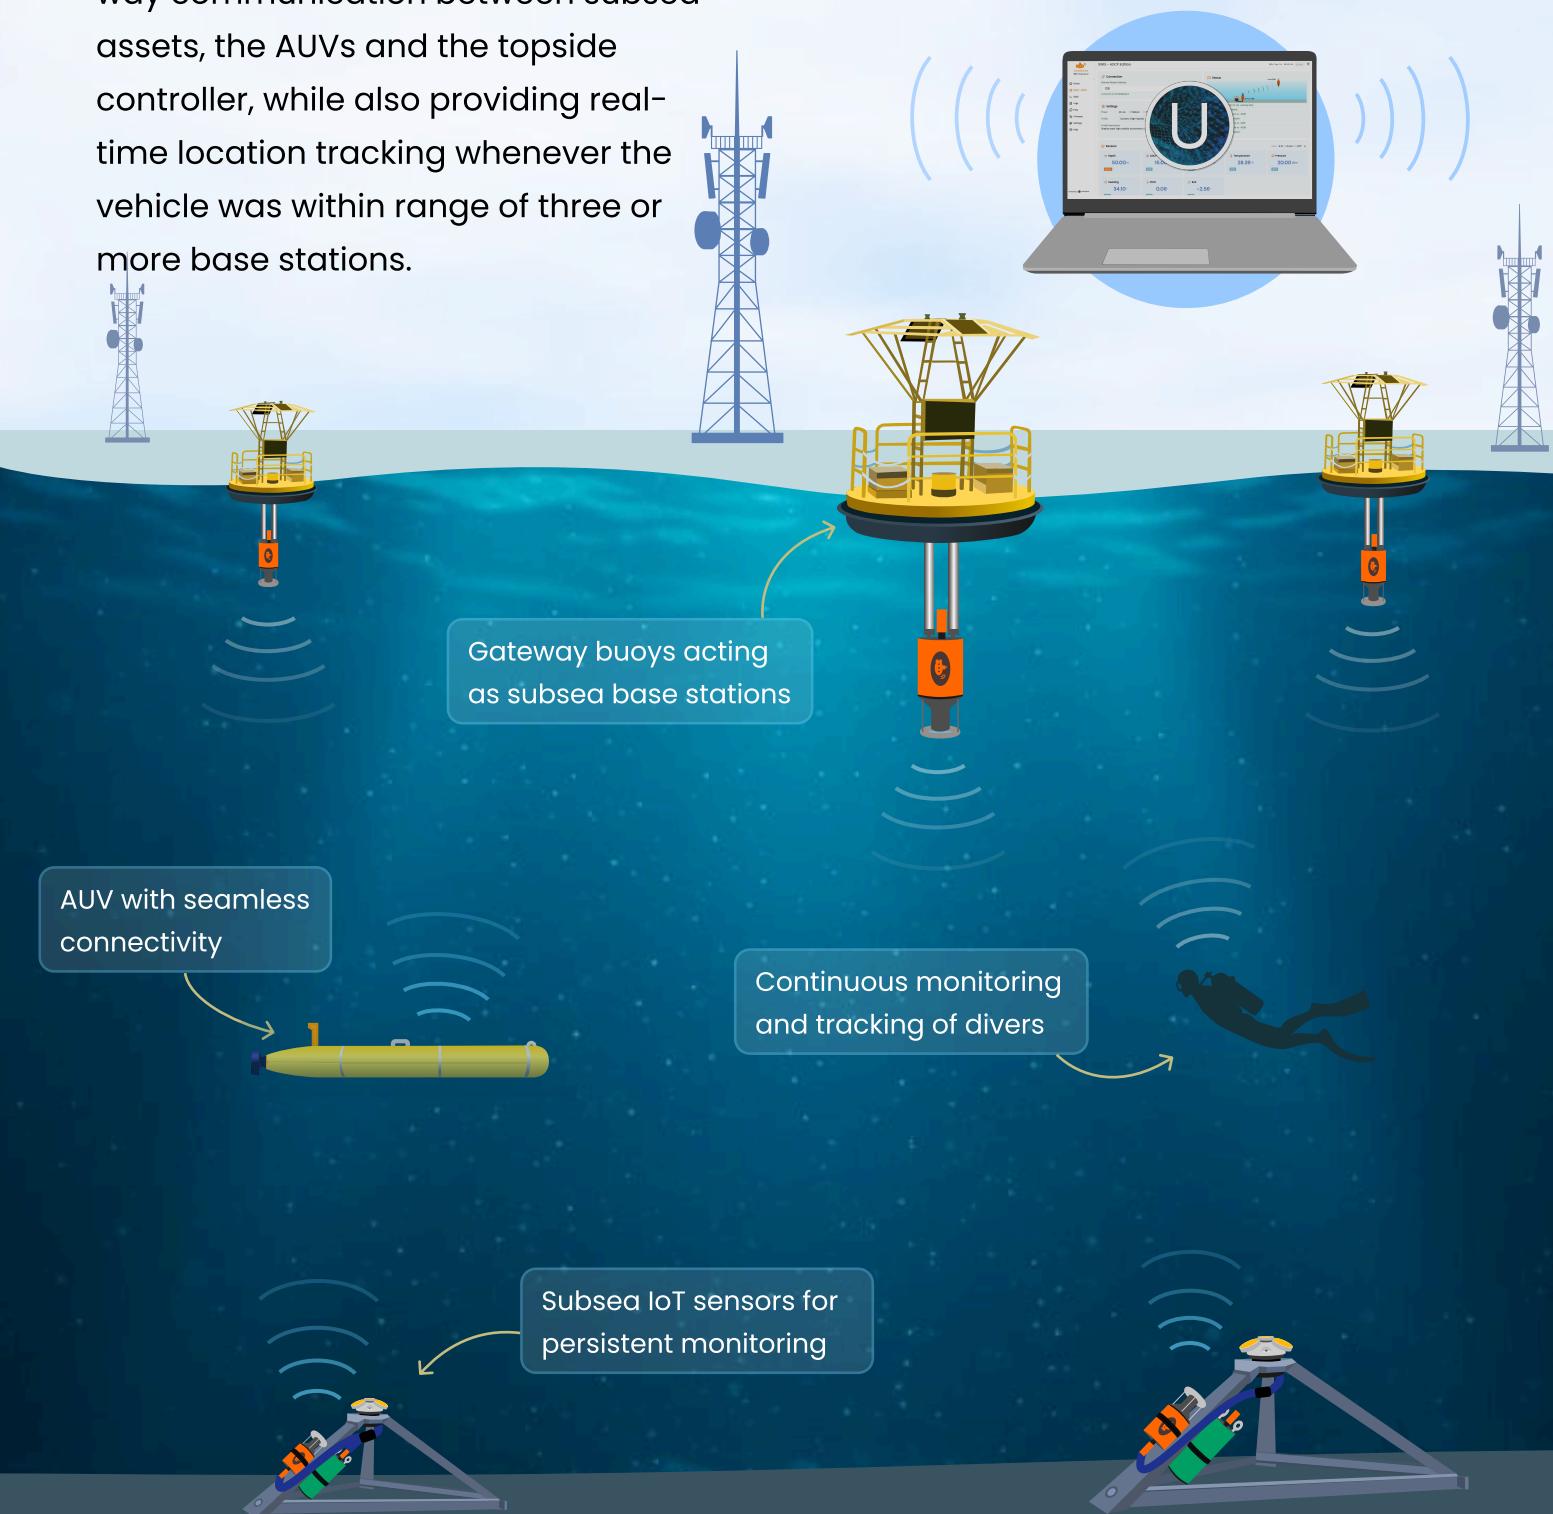

Network Architecture

The network test bed was established using navigational buoys equipped with Subnero's acoustic smart modems, forming subsea base stations. These buoys created overlapping coverage areas, much like cellular towers on land.

This setup enabled continuous two-way communication between subsea assets, the AUVs and the topside controller, while also providing real-time location tracking whenever the vehicle was within range of three or more base stations.

- A three-base-station network was deployed in Singapore waters.
- Underwater assets (e.g. AUVs) equipped with Subnero modems served as the mobile assets utilizing the network.
- A central network controller coordinated the system, enabling communication, handovers, and tracking.

Testbed Trials

- 1 A three-buoy underwater network testbed using Subnero modems was deployed to evaluate cellular-style subsea communication in real conditions.
- 2 AUVs moved between coverage zones and demonstrated seamless handover, maintaining links to the controller.
- 3 Both communication performance (packet transmission, command & control, telemetry) and localization accuracy were monitored.
- 4 The tests were performed jointly by Subnero and ST UIS, demonstrating the system's ability to maintain seamless connectivity and location awareness.

Key Takeaways

Continuous Communication

The testbed maintained stable communication across all trials, supporting uninterrupted data exchange as assets moved between base-station cells. It also demonstrated smooth handovers, much like mobile devices switching between cellular towers.

Continuous Tracking

The network delivered ongoing position updates of the subsea assets whenever coverage allowed, enabling consistent situational awareness throughout operations.

Scalability

The trial confirmed that by deploying additional base stations, the network could be scaled to cover much larger areas, opening new opportunities for subsea operations.

Conclusion

The Singapore deployment marks a major milestone in subsea communications, demonstrating one of the first commercial implementations of underwater cellular networking.

- ↳ Demonstrated that cellular principles can be adapted underwater, enabling continuous communication and tracking of subsea assets.
- ↳ Showcased a joint innovation between Subnero and ST UIS, leveraging acoustic modem technology and network intelligence.
- ↳ Paves the way for a new era of subsea operations, where AUVs, divers, and subsea sensors can remain connected at all times—supporting industries from offshore energy to defense and scientific research.

Perspectives

“ This collaboration has shown that cellular-style networks can bring real-world value to subsea operations. By validating the concept in Singapore’s demanding shallow-water conditions, we are opening the door to scalable solutions for defense, commercial, and research users alike.

Jin Jie Jay Poh
Vice President / Head Unmanned Systems Business Unit
ST Engineering

“ This deployment demonstrates our vision of making subsea communication networks as seamless and versatile as those on land. By enabling resource sharing and continuous connectivity, we are taking the first step toward building the ‘Internet of the Oceans’.
